

## ABSTRACT

In the ADRC processing, a picture is divided into blocks, the maximum value MAX and the minimum value MIN of the pixel value of each block are detected and  $DR = MAX - MIN$  is set as a local dynamic range of each block. The result of ADRC processing obtained by dividing subtracted values obtained by subtracting the minimum value MIN from each pixel value in the block into  $DR/2^k$  is set as an object of various editing processing. Thereby, the almost same editing processing can be conducted comparing with a case where an original picture before ADRC processing is set as the object. Moreover, since the amount of data as the ADRC processing result is little, a load of editing processing can be reduced comparing with the case of setting the original picture before ADRC processing as the object and video processing is performed efficiently.
